Software Design

CSCI-P465/565 (Software Engineering I)

Project Team

Mohit Murali Alumullithody

Tony Dominick Dattolo

Rushikesh Pharate

Rahul Gopichand Shamdasani

1. Introduction

Agile Methodology will be followed to ensure that all the requirement of the customer are met on time and the application works as expected. The team will follow component-based design approach for code-reusability purposes.

1.1 System Description

The team plans to create a social media app which will allow users to create profiles, post images, videos etc. and chat with friends. The team believes that this application will be of significant help to people amid the Covid Pandemic. The team will be focusing on ensuring that the website is clean and intuitive has user-friendly user interface. The team will be delivering the features in agile model, thus incrementally over the period of three months. The technology stack involved will be Django(backend) and React JS(frontend).

1.2 Design Evolution

To ensure that all customer get hassle free experience the team will be focusing towards ensuring that UI component is as simple as possible. All the user must be able to easily login, socialise, post, chat with their friends through the application. To ensure this the team decided to break the core features across various sprints.

1.2.1 Design Issues

Since the project is to be hosted on the internet, A reliable internet connection is expected to use it. Apart from that, The team is expected to implement OAuth 2.0

for Authorisation , which enables users to login through their registered google accounts.

1.2.2 Candidate Design Solutions

Stable Internet Connection : The website will ensure that the users are connected with their friends real time.

OAuth 2.0 : The integration with OAuth 2.0 lets users to create account using their gmail credentials.

Search : The users can search for their interest, friends through the use of search functionality provided in the website.

Dark Mode: The users can switch between two themes for the entire application, One will be Light mode(default mode) another would be dark mode.

1.2.3 Design Solution Rationale

The intention behind using component based approach is that it ensures that the code maintenance cost is low. With proper documentation, code could be reused across various modules as well which would ensure that the team faces no hurdles in development.

1.3 Design Approach

1.3.1 Methods

The team will be following Agile standards during software development and will strictly adhere to agile standards like daily standup, sprint retrospective etc. Each sprint comprising of 2 weeks will be focussed towards developing a working prototype which would then be demonstrated to the client. Component based design pattern will be employed for code maintenance and reusability purposes.

1.3.2 Standards

The team is ensuring that the website developed has clean UI, intuitive and user friendly. The Team is closely following all standard design standards across the market to ensure a seamless experience is provided to the customers.

1.3.3 Tools

FrontEnd : React JS, Next JS
Backend : Python (Django)
Databases : PostgreSQL
Authorisation : OAuth 2.0

2. System Architecture

2.1 System Design

Since the project is a website, Users interact with it through a browser. The front-end is handles by React, which is popular Javascript framework and is integrated tightly with Django framework of python. All the API endpoints are handled by Django framework. During registration process, User can enter details manually which will be saved by the backend in the server or via OAuth. In OAuth, as User clicks on authenticate, corresponding email and password are shared to Google API via OAuth which validates the credentials and returns the basic information of the user along with access tokens to backend ,which then saves it and redirects the user to homepage. In a similar way login functionality is also implemented.

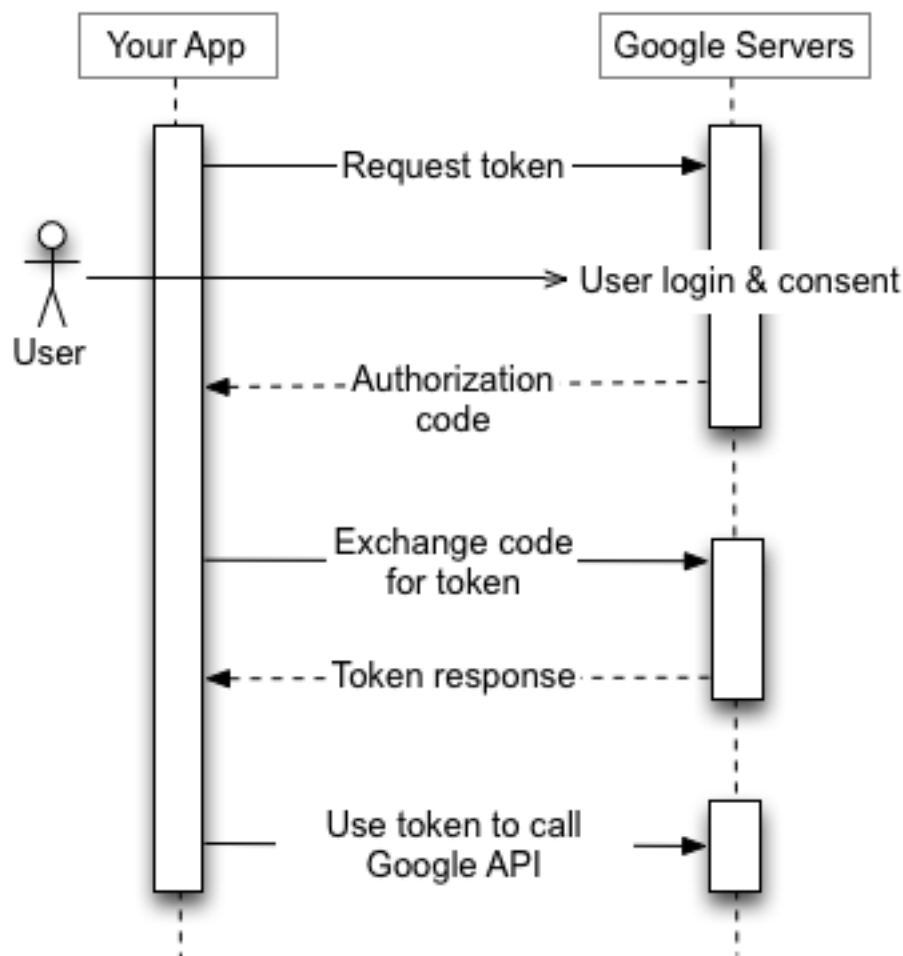

Figure 1 : OAuth Flow, Reference : <https://developers.google.com/identity/protocols/oauth2>

2.2 External Interfaces

Django Framework will be used for implementing backend base code for API calls.
OAuth 2.0 API will be used for Authentication purposes, specific to google accounts.

3. Component Design

- **Component Name**
Authentication Component
Posts Component
Chat Component
Event Pages Component
Search Component
Marketplace Component
Profile Component
Theme Component

- **Component Description**
Authentication Component will be used for registering and logging into the website. It has basic activities involved in logging into any website. It also uses SSO functionality where user can signup/login using their google credentials.

Posts Component aims where once user has logged in can share anything(text or media) through a post on the website.

Chat Component will be used by users to interact with each other through normal text conversations.

Event Pages Component will be used by users where in Users can post details about specific events which will be displayed to all the users who have subscribed to that page.

Search Component will be used by users to search on specific user or group page of their interest.

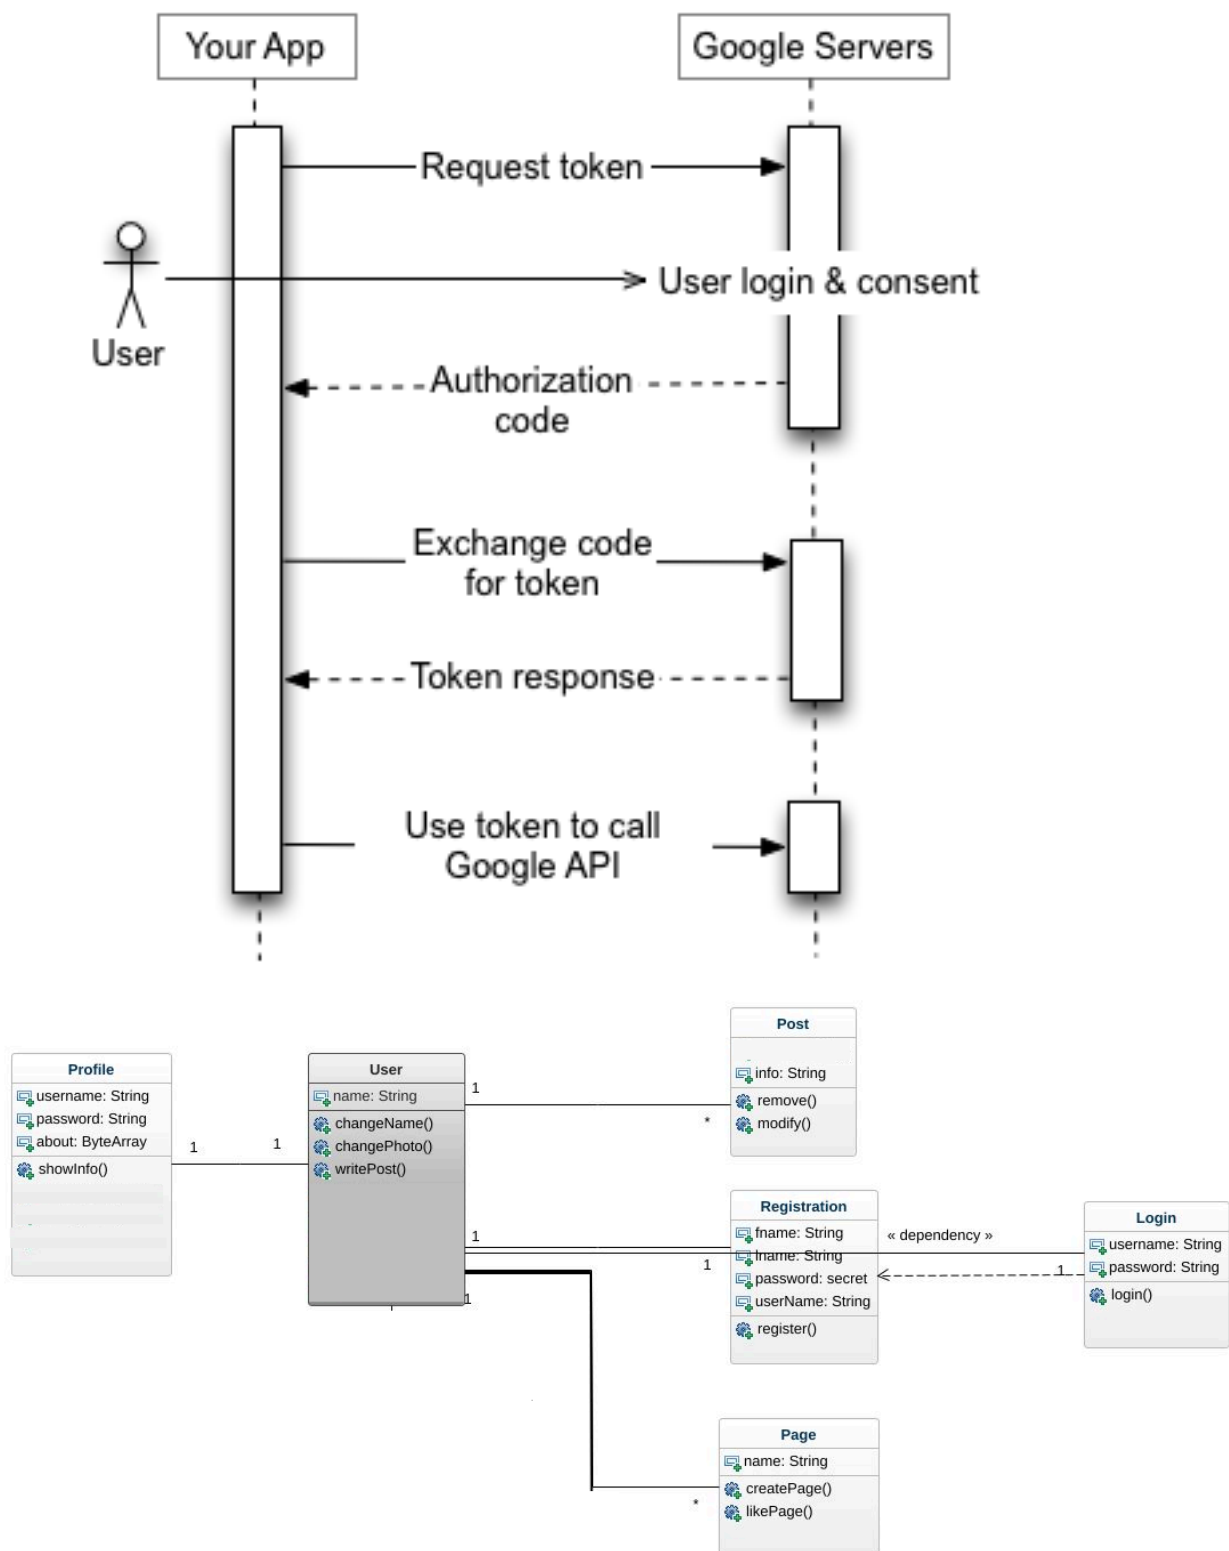

Profile Component will be used by users to view the basic information regarding their profile

Theme Component will be used by user to toggle between Light and Dark mode respectively.

- **Responsible Development Team Lead Member**

Authentication : Mohit
Posts Component : Tony
Chat : Rahul
Events : Rushikesh
Search : Tony
Marketplace : Rushikesh
Profile : Rahul
Dark Mode : Mohit

- **Component Diagram**

- **Component User Interface**

The UI for all the components are HTML Pages. In authentication component, page is similar to a form.

- **Component Objects**

- Authentication component will be called when user tries to login to the website either with credentials or with SSO functionality(i.e. Google accounts). It's also used during the user registration process(Email verification). It will also incorporate reset password functionality through email verification.
- When user tries to login through SSO, a call is made to Google API via the OAuth server, which validates the users and return and redirection url(Homepage in our case if success) along with access tokens and refresh token which are stored in the backend of the system by Django framework.
- Profile component is responsible for loading the basic information page about the user after the user is logged into the system.
- Events component is responsible for loading the basic information page about the specific group which users has searched where details for various events would be reflected.
- Search component is called when logged in users search any specific person or page from search bar.
- Chat component is used for interaction between users through text conversation.
- Posts Component is for ensuring that users can post text or media content onto the system.
- Theme Component will be used by user to toggle between Light and Dark mode respectively.

- **Component Interfaces (internal and external)**

The UI communicates with the backend API which instead communicates with OAuth 2.0 server for authentication purposes.

- **Component Error Handling**

During Signup process, if the user has not entered password which meets the general password format standards, an error will be reflected. During login, if the user enters incorrect email address or password, an error reflecting the same will be shown to the user.

Revision History

Revision	Date	Change Description
1.0	2nd October	Initial Version
2.0	17th October	Modified to incorporate changes from Sprint 2
3.0	25th October	Modified to incorporate changes from Sprint 3
4.0	14th November	Modified to incorporate changes from Sprint 4
5.0	1th December	Modified to incorporate changes from Sprint 5
